

## Data Management

```
library(foreign)
library(rockchalk)
i <- 33
dat <- read.dta(paste("../student-test2/student-", i, ".dta", sep = ""))
```

The variables pprof and pnet are scored as numeric, but really they are factors. So convert them to prevent future mis-understandings.

```
dat$pprof <- factor(dat$pprof, labels = c("NO", "YES"))
dat$pnet <- factor(dat$pnet, labels = c("NO", "YES"))
```

```
datsum <- summarize(dat)
```

Table would need some hand customization

```
library(xtable)
print(xtable(datsum$numeric, caption = "Best Automatic Summary Table for Numerics", label =
"table1"), "latex")
```

	act	harv	ibs	sal1	sal2	sal3	sat

# Aptitude Test Variables

There's severe multicollinearity between the variables harv, sat, and act. It seems clear we can't estimate both sat and harv, and several students noticed that since harv is a summary of the other tests, then there's some reason to suppose sat is a better variable. (I know for a fact that  $\text{harv} = \text{sat} + \text{act}$ ).

Please find Table 2. I left the Iowa Basic Skills variable in my best model, mainly because I wanted to estimate that coefficient, even though the F test below indicates one can exclude harv and ibs from the "full" model without losing any sleep.

```
m1s <- lm(sall ~ sat, data = dat)
m1a <- lm(sall ~ act, data = dat)
m1i <- lm(sall ~ ibs, data = dat)
mlh <- lm(sall ~ harv, data = dat)
m1all <- lm(sall ~ sat + act + ibs + harv, data = dat)
m1best <- lm(sall ~ sat + act + ibs, data = dat)
```

```
mcDiagnose(m1all)
```

```
The following auxiliary models are being estimated and returned in a list:
```

```
sat ~ act + ibs + harv
<environment: 0x2afb118>
act ~ sat + ibs + harv
<environment: 0x2afb118>
ibs ~ sat + act + harv
<environment: 0x2afb118>
harv ~ sat + act + ibs
<environment: 0x2afb118>
```

```
Drum roll please!
```

```
And your R_j Squareds are (auxiliary Rsq)
```

```
    sat      act      ibs      harv
0.9998700 0.8687882 0.2025569 0.9998729
```

```
The Corresponding VIF, 1/(1-R_j^2)
```

```
    sat      act      ibs      harv
7691.454621 7.621266 1.254008 7868.842584
```

```
Bivariate Correlations for design matrix
```

```
    sat  act  ibs  harv
sat  1.00 0.39 0.40 1.00
act  0.39 1.00 0.34 0.41
ibs  0.40 0.34 1.00 0.41
harv 1.00 0.41 0.41 1.00
```

```
niceLabels <- c(act = "ACT", sat = "SAT", harv = "Harvard SS", ibs = "Iowa BS", majorS = "
Major: Soc.", majorN = "Major: Nat.", majorH = "Major: Hum.", pnetYES = "Parent Network
: Yes", pprofYES="Prof. Parents: Yes", genderM = "Gender: Male", "log(harv)"= "ln(
Harvard SS)", "I(harv * harv)"= "Harvard SS$^2$", major2H = "Major 2: Hum.", major2N = "Major 2: Nat.
")
outreg(list(m1s, m1a, m1i, mlh, m1all, m1best), tight = TRUE, modelLabels = c("SAT", "ACT", "
IBS", "Harvard SS", "All", "Best"), varLabels = niceLabels, title = paste("Regression
with sall: Student-", i, sep=""), label = "tab:tab2")
```

Could conduct an F test of the hypothesis that  $b_{ibs} = b_{harv} = 0$ . But which model should I be testing? Test the one with all the variables, to see if *harv* and *ibs* should both be set to 0. To do that, I need to take the data frame used to fit m1all and use it to fit the restricted model. Otherwise, the F test fails.

```
m1alldf <- model.frame(m1all)
m1restricted <- lm(sall ~ sat + act, data = m1alldf)
anova(m1restricted, m1all)
```

```
Analysis of Variance Table
```

```
Model 1: sall ~ sat + act
Model 2: sall ~ sat + act + ibs + harv
```

Table 2: Regression with sal1: Student-33

1	442	1.1133e+10				
2	440	1.1050e+10	2	82745039	1.6474	0.1937

Noticing this sample size problem, I wondered if I should re-do Table 2 so that all are fitted on the exact same data. Since I exclude harv, should those cases that are missing on harv “come back to life” when I exclude harv from the model? I think so. Still, there is something unappetizing about this. Fitting harv causes a loss of cases, no matter how we look at it. So for the best model and the ones for sat and ibs, I use the sample from the best model, but when harv enters the picture, we lose some cases.

```
m1best <- lm(sal1 ~ sat + act + ibs, data = dat)
dat2 <- model.frame(m1best)
m1s <- lm(sal1 ~ sat, data = dat2)
m1a <- lm(sal1 ~ act, data = dat2)
m1i <- lm(sal1 ~ ibs, data = dat2)
mlh <- lm(sal1 ~ harv, data = dat[row.names(dat2), ])
m1all <- lm(sal1 ~ sat + act + ibs + harv, data = dat[row.names(dat2), ])

outreg(list(m1s, m1a, m1i, mlh, m1all, m1best), tight = TRUE, modelLabels = c("SAT", "ACT", "IBS", "Harvard SS", "All", "Best"), varLabels = niceLabels)
```

adj R <sup>2</sup>	0.098	0.055	0.013	0.1	0.118	0.109

\* $p \leq 0.05$

Deciding what's "important"? We have lots of ways. If I've settled on a "best" model, it seems like I should be confined to the variables in that model. And the diagnostics should not depend on harv. Here are the partial and semi-partial correlations.

```
getPartialCor(m1best)
```

sal1
sal1 -1.0000000
sat 0.2437370
act 0.1268652
ibs -0.0369327

```
getDeltaRsquare(m1best)
```

The deltaR-square values: the change in the R-square observed when a single term is removed.
Same as the square of the 'semi-partial correlation coefficient'
deltaRsquare
sat 0.055942719
act 0.014488849
ibs 0.001209809

I admit, it is tough to conceptualize the scales of the different variables. I suppose I could scale the sat, act, and ibs scores so that they are all on the same 0-100 scale. Then I'll re-run the model. (This is called "percent of maximum" scoring (POMS)). Since we KNOW from previous work that re-scaling a variable has absolutely no substantive impact on the fit, and it is just for convenience of interpretation, this is an innocuous change.

```
dat2$satpoms <- 100*(dat2$sat - min(dat2$sat))/(max(dat2$sat) - min(dat2$sat))
dat2$actpoms <- 100*(dat2$act - min(dat2$act))/(max(dat2$act) - min(dat2$act))
dat2$ibspoms <- 100*(dat2$ibs - min(dat2$ibs))/(max(dat2$ibs) - min(dat2$ibs))
summarize(dat2[, c("satpoms", "actpoms", "ibspoms")])
```

F-statistic: 21.72 on 3 and 505 DF,  p-value: 3.044e-13

```

Oh, one more thing. Recall my point that partial and semi-partial correlations are completely worthless when 1) there is multicollinearity and 2) we are uncertain which variables should be in consideration. Notice how crazy your conclusions would be if you based them on the “full” model.
