 - Follow-up tests
- 9 Conclusion

There is no SEM in R base

- Neither R nor any of the required or recommended packages distributed with it include structural equation models. But, ...
- R does include mathematical functions with which SEM estimators can be created

Competing packages

- `sem()` in the “car” package by John Fox. Nearly as old as R itself
- `lavaan`, a package prepared by Yves Rosseel, who intends a function-by-function replication of the results in Mplus
- `OpenMX`, a long-standing matrix calculation framework spearheaded by Steven Bolker, which has been re-written as an R package.
- Various other R packages exist, either as wholesale replacements (`lava`) or as supplementary tools (`semPlot`).

Here we are focused on lavaan

- lavaan is the closest to a “full suite” of SEM tools needed by researchers
- lavaan includes many different estimation algorithms (FIML, WLSMV, etc)
- There is a comprehensive essay, Rosseel, Yves (2012). lavaan: An R Package for Structural Equation Modeling. *Journal of Statistical Software*, 48(2), 1 - 36.
[doi:http://dx.doi.org/10.18637/jss.v048.i02](http://dx.doi.org/10.18637/jss.v048.i02)
- Its author, Yves Rosseel, has demonstrated an extremely high willingness to interact with users and design new features when needs arise

Use affect.rds from summeR-3-2-lm

```
dat <- readRDS("../data/affect.rds")
```

```
head(dat)
```

| | Agency1 | Agency2 | Agency3 | Intrin1 | Intrin2 | Intrin3 | Extrin1 |

Quick Jargon review

Indicators: The observed (aka “manifest”) variables

Latent variables: (aka “factors”, “latent constructs” or “common factors”): unobserved variables thought to be the things we are truly interested in. We’d really like to study the relationship among them, but we are unable to do so.

factor loadings: the coefficients which indicate how tightly an indicator is linked to the latent variable.

lavaan's "model fitting" functions

- The key modeling functions are
 - `lavaan()` : a general model fitter
 - `sem()` : a convenience for fitting structural equation models, receives the input and reformats it to send to `lavaan()`
 - `cfa()` : A convenience that translates input and uses `lavaan()` function in the background

Seemingly overwhelming number of arguments

- The help pages for `sem` and `cfa` list a lot of arguments

```
library(lavaan)  
methods::formalArgs(sem)
```

```
[1] "model"  
[3] "meanstructure"  
[5] "fixed.x"  
[7] "std.lv"  
[9] "std.ov"  
[11] "ordered"  
[13] "sample.cov.rescale"  
[15] "sample.nobs"  
[17] "group"  
[19] "group.equal"  
[21] "group.w.free"  
[23] "constraints"  
[25] "likelihood"  
[27] "information"  
[29] "test"  
[31] "mimic"  
[33] "do.fit"  
"data"  
"conditional.x"  
"orthogonal"  
"parameterization"  
"missing"  
"sample.cov"  
"sample.mean"  
"ridge"  
"group.label"  
"group.partial"  
"cluster"  
"estimator"  
"link"  
"se"  
"bootstrap"  
"representation"  
"control"
```

Seemingly overwhelming number of arguments ...

```
[35] "WLS.V"           "NACOV"  
[37] "zero.add"        "zero.keep.margins"  
[39] "zero.cell.warn"  "start"  
[41] "check"           "verbose"  
[43] "warn"            "debug"
```

- Our mission here is to sort through these, emphasize the important ones, understand that others exist when necessary

The most important arguments

- `model` : a formula (character variable representing a formula)
- `data` : name of data.frame containing variables
- `estimator` : model estimator, defaults to “ML”
- `ordered` : vector of variables to be treated as ordered-categorical

Start with R regression syntax

■ A regression in R:

```
mod1 <- lm(PosAFF1 ~ Agency1 + Intrin1, data =  
  dat)  
summary(mod1)
```

Call:

```
lm(formula = PosAFF1 ~ Agency1 + Intrin1, data = dat)
```

Residuals:

| Min | 1Q | Median | 3Q | Max |
|----------|----------|---------|---------|---------|
| -2.17693 | -0.35887 | 0.05093 | 0.55123 | 1.12382 |

Coefficients:

| | Estimate | Std. Error | t value | Pr(> t) | |
|-------------|----------|------------|---------|----------|-----|
| (Intercept) | 2.05775 | 0.18125 | 11.353 | < 2e-16 | *** |
| Agency1 | 0.18594 | 0.06581 | 2.825 | 0.00497 | ** |
| Intrin1 | 0.20778 | 0.04414 | 4.707 | 3.54e-06 | *** |

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 0.6363 on 377 degrees of freedom

Start with R regression syntax ...

```
Multiple R2: 0.09673, Adjusted R2: 0.09194  
F-statistic: 20.19 on 2 and 377 DF, p-value: 4.693e-09
```

The formula “PosAFF1 ~ Agency1 + Intrin1” is *in* the function call.

- A larger, more elaborate formula can be written as a separate piece, `fmla2`

```
fmla2 <- "PosAFF1 ~ Agency1 + Intrin1"
```

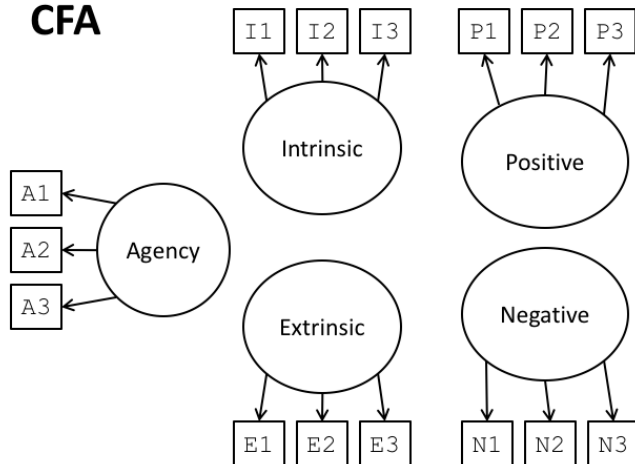

- `fmla2` is a “character string” variable, but the `lm` function understands what to do

```
mod2 <- lm(fmla2, data = dat)
```

- Because structural equation models are almost always “larger” formulas, they are almost always written out as character structures in that style.

Make a lavaan formula for this

CFA

The mathematical formula

- The mathematical model: each indicator is predicted from a latent variable.

$$Agency1_i = \alpha_{11} + \lambda_{11}Agency_i + \varepsilon_{11i}$$

$$Agency2_i = \alpha_{12} + \lambda_{12}Agency_i + \varepsilon_{12i}$$

$$Agency3_i = \alpha_{13} + \lambda_{13}Agency_i + \varepsilon_{13i}$$

$$Extrin1_i = \alpha_{21} + \lambda_{21}Extrinsic_i + \varepsilon_{21i}$$

$$Extrin2_i = \alpha_{22} + \lambda_{22}Extrinsic_i + \varepsilon_{22i}$$

$$Extrin3_i = \alpha_{23} + \lambda_{23}Extrinsic_i + \varepsilon_{23i}$$

Note the book-keeping

- α (alpha) is the “intercept” (expected value when LV is 0)
- λ (beta) is the factor loading
- first subscript is the number of the latent variable, 1 = Agency, 2 = Extrinsic
- second subscript is the number of the indicator

lavaan introduces symbol " \approx "

- In lavaan formulas, the syntax for linkage between measured and unmeasured variables is like so:

```
a_latent_variable  $\approx$  indicator1 + indicator2 +  
  indicator3
```

- We name "a_latent_variable" whatever we want
- "indicator1", "indicator2", "indicator3" must be a variables named in the data frame

```
Agency  $\approx$  Agency1 + Agency2 + Agency3
```

- Note how, while the mathematical formula has $Agency1_i = \alpha + \lambda Agency_i + \varepsilon$, the lavaan formula syntax has the sides reversed

Another lavaan symbol "~~"

- To estimate the covariance between two latent variables, the symbol $\sim\sim$ (that's two tilde) is used.
- For example, we allow the covariance between two latent variables by including this in our formula.

```
latent1  $\sim\sim$  latent2
```

Example model syntax for Confirmatory Factor Analysis

```
cfa.mod <- '  
  Agency =~ Agency1 + Agency2 + Agency3  
  Intrinsic =~ Intrin1 + Intrin2 + Intrin3  
  Extrinsic =~ Extrin1 + Extrin2 + Extrin3  
  Positive =~ PosAFF1 + PosAFF2 + PosAFF3  
  Negative =~ NegAFF1 + NegAFF2 + NegAFF3  
'
```

- You can use single or double quotes
- Line breaks are visual enhancement, which lavaan understands correctly as separate pieces
- Note, we do not include any `~~` symbols here (will return to that topic)

Could instead write out one element per indicator

```
cfa.mod <- '  
  Agency =~ Agency1  
  Agency =~ Agency2  
  Agency =~ Agency3  
  Intrinsic =~ Intrin1  
  Intrinsic =~ Intrin2  
  Intrinsic =~ Intrin3  
  Extrinsic =~ Extrin1  
  Extrinsic =~ Extrin2  
  Extrinsic =~ Extrin3  
  Positive =~ PosAFF1  
  Positive =~ PosAFF2  
  Positive =~ PosAFF3  
  Negative =~ NegAFF1  
  Negative =~ NegAFF2  
  Negative =~ NegAFF3
```

Could instead write out one element per indicator ...

!

- That is verbose, we don't generally write it that way
- This may be easier in very large projects where functions are writing out the formula for us.

Estimate with cfa

```
cfa1 <- cfa(cfa.mod , data = dat)
```

- If there is no output, the model was estimated without errors
- As in other R model fitters, the `summary()` method is used to overview the results

```
summary(cfa1)
```

```
lavaan (0.5–22) converged normally after 66 iterations
```

Why did we use cfa, not lavaan, to fit that?

- As explained in “ ?cfa ”, the cfa function has some default settings that are customary for confirmatory factor analysis.
- The settings are:
 - Estimate observed variable intercepts, set the means of the latent variables to 0, fix the loading for the first indicator to 1 (unless `std.lv = TRUE`), and estimate the covariances between latent variables.
- A very important standard setting for `cfa` is that the covariances are estimated among the latent variables, even though we did not explicitly ask for them.

Variances among the latent variables: "~~"

- Reminder: covariance estimate is requested by `latent1` `~~` `latent2` .
- Did you notice in the output that the `cfa()` function estimated those for us, even though we did not ask for them?
- We could have asked, explicitly, for covariances:

```
cfa.mod2 <- '  
Agency =~ Agency1 + Agency2 + Agency3  
Intrinsic =~ Intrin1 + Intrin2 + Intrin3  
Extrinsic =~ Extrin1 + Extrin2 + Extrin3  
Positive =~ PosAFF1 + PosAFF2 + PosAFF3  
Negative =~ NegAFF1 + NegAFF2 + NegAFF3  
Agency =~ Intrinsic  
Agency =~ Extrinsic  
Agency =~ Positive
```

Variances among the latent variables: "~~" ...

```
Agency ~ Negative  
Intrinsic ~ Extrinsic  
Intrinsic ~ Positive  
Intrinsic ~ Negative  
Extrinsic ~ Positive  
Extrinsic ~ Negative  
Positive ~ Negative  
'
```

```
cfa2 <- cfa(cfa.mod2, data = dat)  
summary(cfa2)
```

Variances among the latent variables: "~~" ...

In lavaan, \sim represents a regression

The symbol $\text{latent1} \sim \text{latent2}$ indicates that one latent variable is predicting another.

We are, in essence, asking SEM to calculate coefficients for a regression model:

$$\text{latent}A_i = \beta_0 + \beta_1 \text{latent}B_i + v_i$$

These slope coefficients represent “directionality”.

Rather than covarying, $\text{latent}B$ predicts $\text{latent}A$ (could be a causal relationship).

Coefficients can be named for future reference

In lavaan formulae, coefficients can be named

$$latentA_i \sim c(beta1) * latentB_i$$

Did you notice loadings = 1.0 in previous output?

- Scaling of latent variables and loading coefficients is our choice
- Previous method is known as the “marker variable” method (Lindell & Whitney, 2001), because for each latent variable a single variable was selected to determine the scale.
- Another commonly used method is to fix the variance of the latent variables at 1.0 (thus allowing the loadings to float freely)

Obtain "standardized latent variable" estimates

```
cfa3 <- cfa(cfa.mod, data = dat, std.lv = TRUE)
```

```
summary(cfa3)
```

```
lavaan (0.5-22) converged normally after 59 iterations
```

Estimation methods

The `estimator` argument in lavaan functions determines the method of estimation

- ML: Maximum likelihood of the complete cases (listwise-delete missings)
 - If `missing = "fiml"`, then Full Information Maximum Likelihood is used to avoid listwise deletion
- WLSMV: weighted least squares with a mean and variance adjustment
 - Standard error estimates that are "robust" to violations of multivariate normality

Bootstrap estimates are also included

- The robust estimators of the standard errors are approximate, but they are widely used.
- lavaan functions include a bootstrap argument
- Why? In small samples, or when parameter distributions are unknown, this is a popular method to evaluate uncertainty.
- The bootstrap estimator will draw repeated random samples and re-estimate the model.

summary

- The `summary()` method in lavaan, as we demonstrated above, generates estimate tables and some summary information.
- Observant readers might have noticed that the default output, obtained from

```
summary( cfa1 )
```

did not include the “fit measures” that are often offered with CFA and SEM output in other software.

- We have several ways to deal with that. We can obtain the fit measures by separate requests, or we can insert the request into the summary call.

summary with additional details

- First, we will insert a request for **fit measures** and the **rsquare** into the summary output. The result looks quite a bit more like Mplus. We select `ci=FALSE` to reduce the width of the output

```
summary(cfa3, rsquare = TRUE, fit.measures = TRUE, ci  
        = FALSE)
```

```
lavaan (0.5–22) converged normally after 59 iterations
```

- What other details could we ask for? We checked the lavaan source code, where we find the summary function allows these flags:
 - header (default: TRUE)
 - fit.measures (default: FALSE)
 - estimates (default: TRUE)
 - ci (default: FALSE)
 - fmi (default: FALSE)
 - standardized (default: FALSE)
 - rsquare (default: FALSE)

summary with additional details ...

- std.nox (default: FALSE)
- modindices (default: FALSE)

parameterEstimates

- The “behind the scenes” work to build `summary` output is done by separate functions which can be accessed directly.
- `parameterEstimates()` is doing most of the actual work in the `summary()` display. It can obtain many, or just a few, elements.
- The relevant arguments for `parameterEstimates()` are
 - `se` (default: TRUE) Show standard errors?
 - `zstat` (default: TRUE) Show Z, ratio of estimate to standard error
 - `pvalue` (default: TRUE) Show p value
 - `ci` (default: TRUE) Show confidence interval
 - `level` (default: 0.95) Confidence level required to calculate ci
 - `boot.ci.type`: (default: “perc”) Confidence interval for bootstrapped models
 - `standardized` (default: FALSE) Add standardized parameter estimates
 - `fmi` (default: FALSE) Show fraction of missing information, for “FIML” models

parameterEstimates ...

- `remove.system.eq` (default: TRUE) Hide user-constrained parameters
 - `remove.eq` (default: TRUE) Hide system-generated constraints
 - `remove.ineq` (default: TRUE) Hide inequality constraints
 - `remove.def` (default: FALSE) Hide parameter definitions
 - `rsquare` (default: FALSE) Add rows for the R-square
- The default output was too wide for these slides, so we don't look at `p` or `ci`. Here are the first 15 lines:

```
parameterEstimates(cfa3, pvalue = FALSE, ci =  
  FALSE)
```

parameterEstimates ...

- Just a few measures? How about the CFI and RMSEA only?

```
fitMeasures(cfa1, fit.measures = c("cfi",
  "rmsea"))
```

```
   cfi rmsea
0.993 0.030
```

fitMeasures ...

- fitMeasures, you will see the list of all possible fit.measures is not fully documented, but it *at least* includes:

```
"cfi", "tli", "nnfi", "pnfi", "rfi", "nfi",  
"ifi", "rmsea", "rmsea.ci.lower", "rmsea.ci.upper",  
"rmsea.pvalue", "rmr", "srmr", "wrmr", "agfi", "pgfi", "mfi", "ecvi",  
"baseline.chisq", "baseline.pvalue", "baseline.df"
```

CFA Commentary

- The model appears to fit well,
 - all factor loadings are significant, and the
 - standardized factor loadings indicate strong correlations between indicators and constructs.
- However, we did not explicitly model the relationships among the latent variables.
 - We don't have "Agency" as predictor of "Positive" affect.
 - The CFA fits "unstructured covariances" between latent variables, not "directional regression relationships".

Other follow-up functions

- Other standard R accessor functions are available in lavaan

```
coef(sem1)  
fitted(sem1)  
resid(sem1)  
anova(sem1)
```

- If you run those things, you will notice some wrinkles.
 - Notice that predicted observations (and residuals) are not 1-per-person
 - `anova()` returns a chi-squared test that indicates there are 0 degrees of freedom (that's an SEM concept).

A nice output table

```
library(kutils)  
semTable(cfa3, fit = c("cfi", "rmsea"))
```

RMSEA = 0.03.

Plots

- There is no plot method for a lavaan object.
- But there are other packages devoted to creating graphics for models that involve path diagrams (e.g., SEM and neural networks).
- The path diagram is visualized here with the `semPaths()` function in `semPlot`.

```
library(semPlot)  
semPaths(cfa1, layout = "tree2")
```

Plots ...

Moderator effects

- Moderators are categorical predictors.
- In a regression context, suppose $Agency_i$ is a continuous predictor of $Positive_i$.

$$Positive_i = \beta_0 + \beta_1 Agency_i, \epsilon_i \sim N(0, \sigma_\epsilon^2) \quad (1)$$

- But we wonder if a categorical variable, $female_i$, causes a change in both the intercept and the slope:

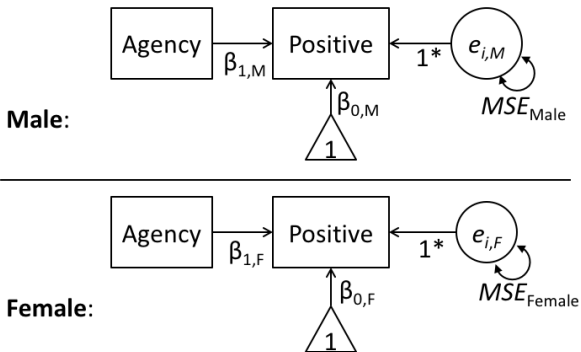

$$Positive_i = \beta_0 + \beta_1 Agency_i + \beta_2 Female_i + \beta_3 Agency_i \cdot Female_i, \epsilon_i \sim N(0, \sigma_\epsilon^2) \quad (2)$$

- Here, the gender is a “**moderator**” of the agency effect

SEM view of the moderator variable

- This sketch segregates the 2 genders entirely; we are estimating 2 separate sets of coefficients.

Moderation with Multiple Groups

2 fits

- Moderation analysis focuses on the differences between groups. In this case, males and females.
- When one of the predictors in an interaction is categorical (e.g., gender), the sem “measurement invariance” approach would lead us to compare
 - a model in which the coefficients for the two groups are assumed to be entirely different, against
 - a simpler model in which some coefficients might be the same

lavaan syntax

```
moderate.mod1 <- 'PosAFF1 ~ c(a, b)*Agency1 '  
out.mod1 <- sem(moderate.mod1, data = dat, group  
  = "Sex")  
summary(out.mod1)
```

Regression relationships among latent variables

- This is the SEM!
- Assume
 - 1 there are “latent variables” (unmeasured personal traits)
 - 2 assume that there is a multivariate normal relationship among those traits
 - 3 the observed scores are a reflection of each individual's latent variables.

The Big Picture

The circles are unmeasured variables.

Mediation among Latent Variables

- The SEM integrates

The Big Picture ...

- “measurement error” analysis with
- analysis of the underlying relationships.

The Little Picture

lavaan model will include named parameters

- agency affects intrinsic motivation

$$Intrinsic = a_1 Agency_i + \epsilon 1_i \quad (3)$$

- positiveAffect is affected by intrinsic motivation and agency

$$Positive = b_1 Intrinsic + c Agency_i + \epsilon 2_i \quad (4)$$

- The product “ $a_1 \cdot b_1$ ” is the indirect effect of agency on posAffect
- See why? Insert equation (3) into (4):

$$\begin{aligned} Positive &= b_1 \{a_1 Agency_i + error_i\} + c Agency_i + \epsilon 2_i \\ &= \{b_1 \cdot a_1\} Agency_i + c Agency_i + \{\epsilon 1_i + \epsilon 2_i\} \end{aligned} \quad (5)$$

- Does the “truth” include just the direct effect c or also the indirect effect $a_1 \cdot b_1$?

The Big lavaan formula

```
mediat.mod.2 <- '  
## measurement model  
Agency =~ Agency1 + Agency2 + Agency3  
Intrinsic =~ Intrin1 + Intrin2 + Intrin3  
Extrinsic =~ Extrin1 + Extrin2 + Extrin3  
Positive =~ PosAFF1 + PosAFF2 + PosAFF3  
Negative =~ NegAFF1 + NegAFF2 + NegAFF3  
## structural model  
Positive ~ b1*Intrinsic + Agency  
Negative ~ b2*Extrinsic  
Intrinsic ~ a1*Agency  
Extrinsic ~ a2*Agency  
Intrinsic =~ Extrinsic  
## define mediation parameters (indirect effects)  
ind1 := a1 * b1  
ind2 := a2 * b2
```

The Big lavaan formula ...

1

Outline

- 1 Overview

- 8 A Path Model
 - Points of Emphasis
 - Estimate with lavaan's sem function
 - Follow-up tests
- 9 Conclusion

1. Named parameters for indirect effect $ind1 = a_1 \cdot b_1$

- The product $a_1 \cdot b_1$ is the indirect effect of Agency on Positive
- Insert equation (3) into (4):

$$\begin{aligned} Positive &= const1 + b_1 \{ const1 + a_1 Agency_i + error_i \} + c Agency_i + \epsilon_{2i} \quad (6) \\ &= \{ const2 + b_1 const1 \} + \{ b_1 \cdot a_1 \} Agency_i + c Agency_i + \{ \epsilon_{1i} + \epsilon_{2i} \} \end{aligned}$$

- Does the “truth” include just the direct effect c or also the indirect effect $a_1 b_1$?

2. Bootstrap the estimate of a_1b_1

- The indirect effect is a_1b_1 , a *product*
- The null hypothesis we would like to test,

$$H_0 : a_1b_1 = 0$$

- At the current time, no analytical “formula” exists for testing that. Instead, it is necessary to use ‘bootstrapped standard errors’.
- The disadvantage of the bootstrap method is that the model must be calculated 100s or 1000s of times (slow!)

Structural Regressions among Latent Constructs

- The arguments for the sem that we focus on are `se` and `bootstrap` .
- Rather than analytically approximate standard errors, the standard deviation of the bootstrapped estimates is used.

```
Nboot <- 500
mediat.out.2 <- sem(mediat.mod.2, data = dat,
                    std.lv = TRUE, se = "boot",
                    bootstrap = Nboot)
summary(mediat.out.2, standardized = TRUE, fit =
        TRUE)
```

Outline

- 1 Overview
- 2 Get the affect data
- 3 lavaan usage
 - Model Formula
 - Other lavaan formula details
 - Coefficient Scaling
 - Estimation Methods
- 4 Explore Fitted lavaan Objects
- 5 Presentable Tables
- 6 Plots
- 7 Moderators
 - Estimate the Moderation Model
- 8 A Path Model
 - Points of Emphasis
 - Estimate with lavaan's sem function
 - Follow-up tests
- 9 Conclusion

Use anova

- The `anova()` function is a generic in R, it is used in many contexts.
- In SEM, it is used to compare models, to conduct an assessment of the extent to which a simpler model fits the data as well as a more detailed model.
- The mediation model with latent variables estimates fewer parameters than the CFA, but it fits just as well as the CFA.

```
anova(cfa3 , mediat.out.2)
```

Chi Square Difference Test

| | Df | AIC | BIC | Chisq | Chisq diff | Df diff |
|--------------|----|--------|--------|--------|------------|---------|
| cfa3 | 80 | 7478.2 | 7635.8 | 106.85 | | |
| mediat.out.2 | 83 | 7474.5 | 7620.3 | 109.15 | 2.3051 | 3 |

Pr(> Chisq)

| | |
|--------------|--------|
| cfa3 | |
| mediat.out.2 | 0.5116 |

Use anova ...

- Intrinsic indicators have the most measurement error (lowest standardized factor loadings). This usually implies more uncertainty about the effect of Intrinsic on other latent variables.

```
summary(mediat.out.2 , standardized = TRUE)
```

```
lavaan (0.5–22) converged normally after 62 iterations
```

Structural Equation Modeling

- In Psychology, SEM has been an area of tremendous growth since 1980.
- SEM is being absorbed slowly into other fields
- The “gold standard” software for SEM modeling is Mplus, although lavaan has succeeded in “matching” side-by-side many of the calculations.
